

AI Metrics Dashboard

Progress toward all coding done through AI agents, measured by share of merged lines — not by whether an agent touched the PR.

Reporting period
Q3 2026 · Sprints 21–26

Observational, not controlled. Agent use rose over the same six sprints in which team tenure grew and the backlog mix changed. These numbers show what happened alongside adoption; they do not isolate AI as the cause. Quality figures use a 30-day lag window so recent sprints aren't flattered by defects that haven't surfaced yet.

Code written by agents ⓘ

43%

of merged lines · goal: 100%

Team using agents ⓘ

4 of 5

devs · was 2 of 5 in sprint 21

PR throughput ⓘ

14/wk

pre-AI baseline: 9/wk

Escaped defect rate ⓘ

9%

30-day lag applied · agent 8% · human 10%

Agent share by work type
How much of each type is already agent-written

Work type	Agent share	Headroom
Boilerplate / CRUD	78%	22% left
Tests	71%	29% left
Feature logic	44%	56% left
Refactors	38%	62% left

Work type	Agent share	Headroom
Bug fixes	22%	78% left
Incident hotfixes	6%	94% left

Sample data for illustration. **Code written by agents** = merged lines whose originating commit carries an agent authorship trailer + total merged lines, via git blame. This replaces the earlier binary "AI-assisted PR" flag, which counted a one-line completion and a fully agent-written PR identically and so could not measure progress toward a percentage-of-work goal. Expect this number to read far lower than PR-level flags did — that is the correction, not a regression. **Team using agents** counts people, not work, and is reported as a fraction to keep it distinct from the line-share percentage. **Escaped defect rate** counts only PRs merged 30+ days ago; defects surface weeks after merge, so without this window recent high-agent sprints appear cleaner simply because their defects have not been found yet. Cycle time runs PR open → merge and excludes QA, staging, and production deploy. Story-point-based speed estimates were removed: points are a subjective input that drifts over time, so measuring "faster" against a points-derived baseline can show improvement from estimate inflation alone.
